Introduction

- We are living for longer with life expectancy having increased substantially - the number of older adults worldwide is expected to triple to two billion in 2050 (United Nations, 2013).
- It is widely accepted that as we get older we will experience some decline in certain aspects of cognitive functioning e.g.
  executive functioning, memory and speed of information processing (Glisky, 2007), and fluid intelligence (Salthouse, 2004).
- Cognitive interventions to ameliorate these cognitive declines have been carried out and have been to some extent successful. However according to systematic reviews carried out by Papp, Walsh and Snyder, 2009 and Reijnders, van Heugtena, van Boktela, 2012 the quality of the interventions were generally judged to be relatively low due to:
  - Poor randomisation methods
  - Lack of matched active controls
  - Few outcome measures/training relate to daily functioning (generalizability of the skills gained)
  - Insufficient follow-up times.

As such the present study assessed whether cognitive training - Computerised Progressive Attention Training (CPAT; Shalev et al., 2007), can be used to improve cognitive functions in ageing in such a way that benefits everyday life.

Method

<table>
<thead>
<tr>
<th></th>
<th>CPAT Group (12 participants)</th>
<th>Control Group (12 participants)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mean Age (sd)</td>
<td>71.6 (7.2)</td>
<td>72.5 (5.7)</td>
</tr>
<tr>
<td>Gender (females)</td>
<td>6</td>
<td>6</td>
</tr>
</tbody>
</table>

Intervention Timeline

<table>
<thead>
<tr>
<th>Measures</th>
<th>Training: 3 hours x 3 weeks</th>
<th>Outcome measures</th>
<th>Follow up: 4 months</th>
</tr>
</thead>
</table>

Baseline/outcome measures:

- Semi structured interview – 13 questions about demographics, pass times and daily functioning
- Cognitive failures questionnaire (Broadbent, Cooper, Fitzgerald & Parkes, 1982) – 25 questions about memory and attention

Objective attention measures

- Global Local Task
  - Executive Attention
  - Sustained Performance Task
  - Peripheral cueing Task
  - Orienting Attention

- Stroop-like Task
  - Executive Attention
  - Search Task
  - Selective Attention

Training

- CPAT Group
  - Sustained Attention
  - Selective Attention
  - Executive Attention

- Control Group

Discussion

- Results indicate improved performance for the CPAT group at Time 2 even for untrained tasks (i.e. Peripheral cueing and Stroop-like).
- The CPAT group shows a general improvement in speed of processing (rather than in a specific attention function), which is a generalizable skill benefiting everyday life.
- Subjective benefit is also shown for the CPAT group, which can lead to increased self efficacy benefiting daily functioning.
- Whilst at follow up the performance of the CPAT group does not remain as substantial as it was at Time 2 for some measurements, an improvement in comparison to Time 1 remains evident.
- Results thus suggest that attention training in older adults is efficacious.
- Future studies should investigate the effect of longer training sessions. As well as compare younger adults with trained older adults.

Results

Cognitive failures questionnaire

N.B. Higher scores represent greater frequency of cognitive failures

Global Local Task

- Continued Performance Task

Peripheral Cueing Task

Search
